

Transverse Instability of Solitons Propagating on Current-Carrying Metal Thin Films

R. Mark Bradley

Department of Physics, Colorado State University, Fort Collins, CO 80523 USA

Abstract

Small amplitude, long waves travelling over the surface of a current-carrying metal thin film are studied. The equation of motion for the metal surface is determined in the limit of high applied currents, when surface electromigration is the predominant cause of adatom motion. If the surface height h is independent of the transverse coordinate y , the equation of motion reduces to the Korteweg-de Vries equation. One-dimensional solitons (i.e., those with h independent of y) are shown to be unstable against perturbations to their shape with small transverse wavevector.

Key words: soliton stability, electromigration, metal surfaces

1 Introduction

The motion of the free surface of an incompressible fluid has been the subject of much research, from the 19th century to the present day. Of the many fascinating phenomena that have been investigated, soliton propagation is certainly among the most intriguing [1,2].

Solitons were first observed in 1834 by John Scott Russell on the surface of a narrow, water-filled canal [3]. It was not until 1895, however, that it was demonstrated that solitons are solutions to the Korteweg-de Vries (KdV) equation, the equation of motion for small amplitude, long gravity waves [4].

Although it is not yet widely appreciated, there are nontrivial *electrical* free boundary problems. When an electrical current passes through a piece of solid metal, collisions between the conduction electrons and the metal atoms at the surface lead to drift of these atoms. This phenomenon, which is known as surface electromigration (SEM), can cause a solid metal surface to move and deform [5–15]. The free surface of a metal film moves in response to the

electrical current flowing through the bulk of the film, in much the same way that flow in the bulk of a fluid affects the motion of its surface. However, the analogy is not perfect — the boundary conditions are very different in the two problems.

Just as solitary waves can propagate over the surface of a shallow body of water, solitons can propagate over the free surface of a current-carrying metal thin film [9,12,13,16]. Let the applied electric field be in the x direction and take the z axis to be normal to the undisturbed metal surface. If the surface height h is independent of y , the equation of motion for small amplitude, long waves on the free surface is the KdV equation in the limit of high applied currents [16]. The “one-dimensional” solitons satisfying the KdV equation are protrusions that propagate in the direction of the applied electric field. Their velocity decreases linearly with amplitude; in contrast, the velocity of a soliton on the free surface of a body of water increases with amplitude.

A soliton propagating along a narrow, shallow channel of water is stable against small perturbations to its shape [17,18]. The issue of whether or not a one-dimensional (1D) soliton is stable is more complex if it is travelling over the surface of a sheet of water. The equation of motion for weakly two-dimensional, small amplitude, long waves on a fluid sheet is the Kadomtsev-Petviashvili (KP) equation

$$(u_t + 6uu_x + u_{xxx})_x + 3\sigma^2 u_{yy} = 0, \quad (1)$$

where $u_x \equiv \partial u / \partial x$ and so forth [2]. The KP equation reduces to the KdV equation if u is independent of y . In the regime in which the effects of gravity dominate those of surface tension, $\sigma^2 = +1$ and the equation of motion is known as the KP-II equation. 1D solitons are stable in this case [19]. The equation of motion in the regime in which surface tension is dominant is Eq. (1) with $\sigma^2 = -1$, i.e., the KPI equation. In this case, the 1D solitons are unstable [19].

The KP equation is not the only possible generalization of the KdV equation to two dimensions. The Zakharov-Kuznetsov (ZK) equation

$$u_t + (u_{xx} + u_{yy})_x + uu_x = 0 \quad (2)$$

is another; it describes deviations from the average ion density in an ion-acoustic plasma permeated by a strong uniform magnetic field [20]. In this case, 1D solitons are unstable against perturbations of sufficiently long transverse wavelength [21–25].

To what extent does electromigration-induced soliton propagation resemble soliton propagation over the free surface of a fluid? Consider a long, rectangu-

lar, current-carrying ribbon of metal. Suppose that the metal ribbon has small thickness, and that it is passivated along all but one edge (Fig. 1). Solitons travelling along the free surface of the metal film satisfy the KdV equation and are stable [16–18] — this is the analog of a soliton moving along a narrow channel of water.

Figure 1. Cross section of the metal ribbon. The passivating layer (shown in black) is an electrical insulator and covers all but one edge of the ribbon (shown in gray). Since the thickness d of the ribbon is small, the location of the free surface of the metal is to a good approximation independent of y . The electric field points in the x direction if the free surface is undisturbed.

As we have seen, a 1D soliton travelling over the surface of a fluid sheet may or may not be stable, depending on the value of the surface tension. We now pose the analogous question for electromigration: Is a 1D soliton travelling over the surface of a metal thin film of infinite extent stable? Answering this question is the primary goal of this paper.

To begin, we shall determine the equation of motion for small amplitude, long waves on the surface of a current-carrying metal film for the general case in which the surface height h depends on both x and y . This equation differs from both the KP and ZK equations, and seems not to have been studied previously. We then demonstrate that the one-dimensional solitons are unstable against perturbations with small transverse wavevector.

2 Equations of motion

Consider a metal film of thickness h_0 deposited on the plane surface of an insulating substrate. We take the z axis to be normal to the substrate surface and locate the origin in this plane. A constant current flows through the film in the x direction, and the electric field within the metal is $E_0\hat{x}$.

Now suppose that the upper surface of the film is perturbed (Fig. 2). Let the outward-pointing unit normal to this surface be $\hat{n}$. The height of the film's surface above the substrate h depends on x , y and t . The upper film surface will evolve in the course of time due to the effects of SEM and surface self-diffusion. We assume that the current flowing through the film is held fixed.

Figure 2. The current-carrying metal thin film. The height of the free surface above the substrate, h , depends on x , y and t . The outward-pointing unit normal to the free surface is $\hat{n}$, and the electric field far from the perturbation is $\vec{E}_0$.

The electrical potential $\Phi = \Phi(x, y, z, t)$ satisfies the Laplace equation

$$\nabla^2 \Phi = 0 \quad (3)$$

and is subject to the boundary condition $\hat{n} \cdot \vec{\nabla} \Phi = 0$ on the upper surface and $\hat{z} \cdot \vec{\nabla} \Phi = 0$ on the lower. More explicitly, we have

$$\Phi_z(x, y, h, t) = h_x \Phi_x(x, y, h, t) + h_y \Phi_y(x, y, h, t) \quad (4)$$

and

$$\Phi_z(x, y, 0, t) = 0. \quad (5)$$

If the initial perturbation is localized in the x direction, we will also have

$$h(x, y, t) \rightarrow h_0 \quad (6)$$

for $x \rightarrow \pm\infty$ and, furthermore,

$$\Phi_x(x, y, z, t) \rightarrow -E_0, \quad (7)$$

and

$$\Phi_y(x, y, z, t) \rightarrow 0 \quad (8)$$

for $x \rightarrow \pm\infty$, arbitrary y , and $0 \leq z \leq h_0$.

We assume that the mobility of the metal atoms is negligible at the metal-insulator interface, so that the form of that interface remains planar for all time. Further, in the interest of simplicity, we assume that the applied current is high enough that the effects of SEM are much more important than those of capillarity. The surface atomic current $\vec{J}_a$ is then proportional to the electrical current at the surface. Explicitly, $\vec{J}_a = -\nu M q \vec{\nabla} \Phi$, where the ν is the areal density of the mobile surface atoms, q is their effective charge, and M , the adatom mobility, will be assumed to have negligible anisotropy. When there is a net influx of atoms into a small surface element, the surface element will move. The normal velocity of the metal surface is

$$v_n = q M \nu \Omega \nabla_S^2 \Phi, \quad (9)$$

where Ω is the atomic volume and ∇_S^2 is the surface (Beltrami) Laplacian [26]. Note that $h_t = \sqrt{g} v_n$, where $g \equiv 1 + h_x^2 + h_y^2$ is the determinant of the metric tensor for the surface. Using this relation and writing out the surface Laplacian explicitly, we have

$$\begin{aligned} \frac{1}{q M \nu \Omega} \frac{\partial h}{\partial t} = & \partial_x \left\{ \frac{1}{\sqrt{g}} [(1 + h_y^2) \partial_x - h_x h_y \partial_y] \Phi(x, y, h, t) \right\} \\ & + \partial_y \left\{ \frac{1}{\sqrt{g}} [(1 + h_x^2) \partial_y - h_x h_y \partial_x] \Phi(x, y, h, t) \right\}. \end{aligned} \quad (10)$$

Here ∂_x is the total derivative with respect to x , and ∂_y is similarly defined. (Since h depends on x , we have $\partial_x \Phi(x, y, h, t) = \Phi_x(x, y, h, t) + h_x \Phi_z(x, y, h, t)$,

for example.) Together, Eqs. (3) - (10) completely describe the nonlinear dynamics of the film surface.

3 Asymptotic analysis

We wish to study the propagation of a localized disturbance whose amplitude is small compared to h_0 , and whose width is much larger than h_0 . To do so, we will use multiple scale asymptotic analysis [1]. We put $h = h_0 + a\zeta$, where the constant a is a measure of the amplitude of the disturbance and $\zeta = \zeta(x, y, t)$ is of order unity. Let l be the characteristic width of the initial disturbance. We will study the limit in which both $\alpha \equiv a/h_0$ and $\delta \equiv h_0/l$ are small. More precisely, we shall consider the limit in which α and δ tend to zero, but α/δ^2 remains finite. It is in this limit that the effects of nonlinearity and dispersion balance, and solitons can propagate.

To simplify the description of the problem, we will set $\Phi = -E_0x + \phi$, so that $\vec{\nabla}\phi \rightarrow 0$ for $x \rightarrow \pm\infty$. We also introduce the dimensionless quantities $\tilde{x} \equiv x/l$, $\tilde{y} \equiv y/l$, $\tilde{z} \equiv z/h_0$, $\tilde{t} \equiv (|q|ME_0\nu\Omega/h_0l)t$, and $\tilde{\phi}(\tilde{x}, \tilde{y}, \tilde{z}, \tilde{t}) \equiv \phi(x, y, z, t)/(E_0l)$. Eq. (3) becomes

$$\tilde{\phi}_{\tilde{z}\tilde{z}} + \delta^2(\tilde{\phi}_{\tilde{x}\tilde{x}} + \tilde{\phi}_{\tilde{y}\tilde{y}}) = 0, \quad (11)$$

which applies for $0 \leq \tilde{z} \leq 1 + \alpha\zeta(\tilde{x}, \tilde{y}, \tilde{t})$ and all $\tilde{x}$ and $\tilde{y}$. The boundary conditions are

$$\tilde{\phi}_{\tilde{z}} = 0 \quad \text{for } \tilde{z} = 0, \quad (12)$$

$$\tilde{\phi}_{\tilde{z}} = \alpha\delta^2(\tilde{\phi}_{\tilde{x}} - 1)\zeta_{\tilde{x}} + \alpha\delta^2\tilde{\phi}_{\tilde{y}}\zeta_{\tilde{y}} \quad \text{for } \tilde{z} = 1 + \alpha\zeta(\tilde{x}, \tilde{y}, \tilde{t}), \quad (13)$$

$$\zeta \rightarrow 0 \quad \text{for } \tilde{x} \rightarrow \pm\infty, \quad (14)$$

and

$$\tilde{\phi}_{\tilde{x}}\hat{x} + \tilde{\phi}_{\tilde{y}}\hat{y} \rightarrow 0 \quad \text{for } 0 \leq \tilde{z} \leq 1 \text{ and } \tilde{x} \rightarrow \pm\infty. \quad (15)$$

Finally, the equation of motion for the free surface of the film is

$$\begin{aligned} \sigma_q\alpha\zeta_{\tilde{t}} = \partial_{\tilde{x}} \left\{ \frac{1}{\sqrt{g}} \left[(1 + \alpha^2\delta^2\zeta_{\tilde{y}}^2)(\partial_{\tilde{x}}\tilde{\phi} - 1) - \alpha^2\delta^2\zeta_{\tilde{x}}\zeta_{\tilde{y}}\partial_{\tilde{y}}\tilde{\phi} \right] \right\} \\ + \partial_{\tilde{y}} \left\{ \frac{1}{\sqrt{g}} \left[(1 + \alpha^2\delta^2\zeta_{\tilde{x}}^2)\partial_{\tilde{y}}\tilde{\phi} - \alpha^2\delta^2\zeta_{\tilde{x}}\zeta_{\tilde{y}}(\partial_{\tilde{x}}\tilde{\phi} - 1) \right] \right\}, \end{aligned} \quad (16)$$

where $\tilde{z} = 1 + \alpha\zeta(\tilde{x}, \tilde{y}, \tilde{t})$ and $\sigma_q \equiv q/|q|$. Note that $g = 1 + \alpha^2\delta^2(\zeta_{\tilde{x}}^2 + \zeta_{\tilde{y}}^2)$.

We next introduce the scaled variables

$$\xi \equiv \frac{\alpha^{1/2}}{\delta}(\tilde{x} + \sigma_q \tilde{t}), \quad (17)$$

$$\eta \equiv \frac{\alpha^{1/2}}{\delta}\tilde{y}, \quad (18)$$

$$\tau \equiv \frac{\alpha^{3/2}}{\delta}\tilde{t}, \quad (19)$$

and

$$\psi \equiv \frac{\alpha^{1/2}}{\delta}\tilde{\phi}. \quad (20)$$

(ξ, η, τ) is a moving coordinate system that translates with velocity $v_0 \equiv -qME_0\nu\Omega/h_0$ relative to the laboratory frame. v_0 is the velocity of surface waves in the limit of vanishing amplitude and wavevector [9].

For convenience, we drop the tilde on z . Laplace's equation becomes

$$\psi_{zz} + \alpha(\psi_{\xi\xi} + \psi_{\eta\eta}) = 0, \quad (21)$$

and this applies for $0 \leq z \leq 1 + \alpha\zeta(\xi, \eta, \tau)$ and all ξ and η . In terms of the scaled variables, Eqs. (12) - (16) are

$$\psi_z = 0 \quad \text{for } z = 0, \quad (22)$$

$$\psi_z = \alpha^2[(\psi_\xi - 1)\zeta_\xi + \zeta_\eta\psi_\eta] \quad \text{for } z = 1 + \alpha\zeta(\xi, \eta, \tau), \quad (23)$$

$$\zeta \rightarrow 0 \quad \text{for } \xi \rightarrow \pm\infty, \quad (24)$$

$$\psi_\xi\hat{x} + \psi_\eta\hat{y} \rightarrow 0 \quad \text{for } 0 \leq z \leq 1 \text{ and } \xi \rightarrow \pm\infty, \quad (25)$$

and

$$\begin{aligned} \alpha\zeta_\xi + \sigma_q\alpha^2\zeta_\tau = \partial_\xi \left\{ \frac{1}{\sqrt{g}} \left[(1 + \alpha^3\zeta_\eta^2)(\partial_\xi\psi - 1) - \alpha^3\zeta_\xi\zeta_\eta\partial_\eta\psi \right] \right\} \\ + \partial_\eta \left\{ \frac{1}{\sqrt{g}} \left[(1 + \alpha^3\zeta_\xi^2)\partial_\eta\psi - \alpha^3\zeta_\xi\zeta_\eta(\partial_\xi\psi - 1) \right] \right\} \end{aligned} \quad (26)$$

for $z = 1 + \alpha\zeta(\xi, \eta, \tau)$. In terms of the scaled variables, $g = 1 + \alpha^3(\zeta_\xi^2 + \zeta_\eta^2)$. One advantage of introducing the scaled variables is now manifest: δ does not appear explicitly in Eqs. (21) - (26).

We shall now begin our analysis of the small α limit. We assume that for small α and fixed ξ and τ , there is a solution with

$$\zeta = \sum_{n=0}^{\infty} \alpha^n \zeta_n(\xi, \eta, \tau) \quad (27)$$

and

$$\psi = \sum_{n=0}^{\infty} \alpha^n \psi_n(\xi, \eta, \tau, z), \quad (28)$$

where the ζ_n 's and ψ_n 's are independent of α .

We next insert the expansions (27) and (28) into Eqs. (21) - (26) and equate terms of the same order in α . The goal will be to find a closed integral equation for ζ_0 . We will need to consider terms up to order α^3 . To prepare for this task, we note that to third order in α , Eq. (23) is

$$\begin{aligned} \psi_z + \alpha\zeta\psi_{zz} + \frac{1}{2}\alpha^2\zeta^2\psi_{zzz} + \frac{1}{6}\alpha^3\zeta^3\psi_{zzzz} \\ = \alpha^2(\psi_\xi + \alpha\zeta\psi_{\xi z} - 1)\zeta_\xi + \alpha^2\zeta_\eta\psi_\eta + \alpha^3\zeta\zeta_\eta\psi_\eta. \end{aligned} \quad (29)$$

This result holds for $z = 1$. To second order in α , Eq. (26) reduces to

$$\alpha\zeta_\xi(\xi, \eta, \tau) + \sigma_q\alpha^2\zeta_\tau(\xi, \eta, \tau) = (\partial_\xi^2 + \partial_\eta^2)\psi(\xi, \eta, 1 + \alpha\zeta, \tau). \quad (30)$$

We begin by working to zeroth order in α . To this order, Eq. (21) becomes $\psi_{0zz} = 0$ for $0 \leq z \leq 1$. This implies that ψ_{0z} does not depend on z . Applying Eq. (22), we see that in fact $\psi_{0z} = 0$ for all z , ξ , η and τ . We conclude that ψ_0 depends only on ξ , η and τ , and we write

$$\psi_0 = \theta_0(\xi, \eta, \tau). \quad (31)$$

The boundary condition at the free surface of the film gives no new information to zeroth order in α , as is readily seen from Eq. (29).

We now insert the expansions (27) and (28) into Eq. (30) and simplify using the fact that $\psi_{0z} = 0$. This gives

$$\alpha\zeta_\xi + \sigma_q\alpha^2\zeta_\tau = \psi_{\xi\xi} + \psi_{\eta\eta} + \alpha^2(\zeta_0\psi_{1\xi\xi z} + 2\zeta_{0\xi}\psi_{1\xi z} + \zeta_{0\xi\xi}\psi_{1z} + \zeta_0\psi_{1\eta\eta z} + 2\zeta_{0\eta}\psi_{1\eta z} + \zeta_{0\eta\eta}\psi_{1z}) \quad (32)$$

for $z = 1$. Eq. (32) is valid to second order in α .

Armed with this result, we return to the zeroth order analysis. To that order, Eq. (32) reduces to

$$\theta_{0\xi\xi} + \theta_{0\eta\eta} = 0. \quad (33)$$

Now both $\theta_{0\xi}$ and $\theta_{0\eta}$ must vanish for $|\xi| \rightarrow \infty$. The only solution to Eq. (33) that satisfies these boundary conditions is the trivial one: θ_0 is a constant for all ξ and η . Because the zero of the electrical potential is arbitrary, we may set this constant to zero.

To first order in α , we find that ψ_1 is independent of z . We shall write

$$\psi_1 = \theta_1(\xi, \eta, \tau). \quad (34)$$

Eq. (29) again yields no new information. The equation of motion (32) is to first order

$$\theta_{1\xi\xi} + \theta_{1\eta\eta} = \zeta_{0\xi}. \quad (35)$$

Our next task will be to write out the equations of motion to order α^2 . Eqs. (21) and (35) show that

$$\psi_{2zz} = -(\theta_{1\xi\xi} + \theta_{1\eta\eta}) = -\zeta_{0\xi} \quad (36)$$

for $0 \leq z \leq 1$. Integrating this with respect to z and using the boundary condition at the metal-insulator interface (22), we have $\psi_{2z} = -\theta_{0\xi}z$. Integrating once again, we obtain

$$\psi_2 = \theta_2 - \frac{1}{2}\zeta_{0\xi}z^2, \quad (37)$$

where θ_2 depends only on ξ , η and τ . Once more, Eq. (29) tells us nothing new. Eq. (32) simplifies considerably now that we know that $\psi_{1z} = 0$. Using Eq. (37) as well, we obtain

$$\sigma_q\zeta_{0\tau} + \frac{1}{2}(\zeta_{0\xi\xi\xi} + \zeta_{0\xi\eta\eta}) = \theta_{2\xi\xi} + \theta_{2\eta\eta} - \zeta_{1\xi}. \quad (38)$$

Equating terms of order α^3 in Eq. (21) yields $\psi_{3zz} + \psi_{2\xi\xi} + \psi_{2\eta\eta} = 0$ for $0 \leq z \leq 1$. Integrating this twice with respect to z and applying Eqs. (22) and (37), we find that

$$\psi_3 = \theta_3 - \frac{1}{2}(\theta_{2\xi\xi} + \theta_{2\eta\eta})z^2 + \frac{1}{24}(\zeta_{\xi\xi\xi} + \zeta_{0\xi\eta\eta})z^4, \quad (39)$$

where $0 \leq z \leq 1$ and $\theta_3 = \theta_3(\xi, \eta, \tau)$. We next equate terms of third order in Eq. (29). We obtain

$$\psi_{3z} + \zeta_0 \psi_{2zz} = -\zeta_{1\xi} + \psi_{1\xi} \zeta_{0\xi} + \zeta_{0\eta} \psi_{1\eta} \quad (40)$$

for $z = 1$. This can be simplified using Eqs. (34), (37), and (39). The result is

$$\theta_{2\xi\xi} + \theta_{2\eta\eta} - \zeta_{1\xi} = \frac{1}{6}(\zeta_{0\xi\xi\xi} + \zeta_{0\xi\eta\eta}) - \zeta_0 \zeta_{0\xi} - \theta_{1\xi} \zeta_{0\xi} - \theta_{1\eta} \zeta_{0\eta}. \quad (41)$$

Comparing this with Eq. (38), we have

$$\sigma_q \zeta_{0\tau} + \frac{1}{3}(\zeta_{0\xi\xi} + \zeta_{0\eta\eta})_\xi + \zeta_0 \zeta_{0\xi} = -(\theta_{1\xi} \zeta_{0\xi} + \theta_{1\eta} \zeta_{0\eta}). \quad (42)$$

Since we have assumed that the disturbance is localized, ζ_0 , $\theta_{1\xi}$ and $\theta_{1\eta}$ must all tend to zero as $\xi \rightarrow \pm\infty$.

Equations (35) and (42) are a closed system of equations that describe the dynamics of the film surface in the small amplitude, long wavelength limit. These equations represent a considerable simplification of the problem: in the original formulation, the 3D Laplace equation for $\Phi = \Phi(x, y, z, t)$ would have to be solved subject to boundary conditions at a moving boundary, a stationary plane boundary, and at infinity. In the simplified description of the problem, a Poisson equation for $\theta_1 = \theta_1(\xi, \eta, \tau)$ [i.e., Eq. (35)] must be solved subject only to the boundary conditions at infinity.

If the film height is independent of η , Eq. (35) reduces to $\theta_{1\xi\xi} = \zeta_{0\xi}$. Integrating this with respect to ξ yields $\theta_{1\xi} = \zeta_0 + F$, where F is a function of τ . Both $\theta_{1\xi}$ and ζ_0 tend to zero as ξ becomes large, and hence $F(\tau) = 0$ for all τ . Eq. (42) may therefore be rewritten as follows:

$$\sigma_q \zeta_{0\tau} + \frac{1}{3} \zeta_{0\xi\xi\xi} + 2\zeta_0 \zeta_{0\xi} = 0. \quad (43)$$

Thus, when the film height is independent of η , the equation of motion is the KdV equation, just as we found in Ref. [16].

Before continuing, we shall simplify our notation somewhat. Let $X = \sigma_q \xi$, $Y = \eta$, $T = \tau/3$, $u = 6\zeta_0$, and $\Psi = 6\sigma_q \theta_1$. Equations (35) and (42) become

$$u_T + (\partial_X^2 + \partial_Y^2)u_X + \frac{1}{2}uu_X = -\frac{1}{2}(\Psi_X u_X + \Psi_Y u_Y) \quad (44)$$

and

$$\Psi_{XX} + \Psi_{YY} = u_X. \quad (45)$$

The solution to Eq. (45) that satisfies the requirement that $\Psi_X \hat{x} + \Psi_Y \hat{y}$ tend to zero for $X \rightarrow \pm\infty$ is

$$\Psi(X, Y) = \frac{1}{4\pi} \int_{-\infty}^{\infty} dX' \int_{-\infty}^{\infty} dY' \ln[(X - X')^2 + (Y - Y')^2] u_X(X', Y'). \quad (46)$$

Insertion of this result into Eq. (44) yields a closed integral equation for u ; finding such a relation was the goal of this section. However, we will find it more convenient to work with Eqs. (44) and (45) rather than this unwieldy integral equation.

SEM does not create or destroy atoms — it simply moves them across the metal surface. The total mass, which is proportional to $\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} h(x, y, t) dx dy$, is therefore conserved. This conservation law was not lost in the asymptotic analysis: Eqs. (44) and (45) imply that $\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} u(X, Y, T) dX dY$ is a constant. Indeed, using Eq. (45), Eq. (44) can be written

$$u_T + \vec{\nabla} \cdot \vec{J} = 0, \quad (47)$$

where $\vec{\nabla} \equiv \partial_X \hat{X} + \partial_Y \hat{Y}$ and

$$\vec{J} \equiv \vec{\nabla} u_X + \frac{1}{2} u \vec{\nabla} \Psi. \quad (48)$$

Eq. (47) is the local statement of mass conservation and $\vec{J}$ is the current of the conserved quantity u .

Equations (44) and (45) have soliton solutions given by

$$u = 12a^2 \text{sech}^2[a(X - X_0 - 4a^2 T)] \quad (49)$$

and

$$\Psi = 12a \tanh[a(X - X_0 - 4a^2 T)], \quad (50)$$

where a and X_0 are constants. In the next section, we will demonstrate that these one-dimensional solitons are unstable against long-wavelength perturbations.

If we set the right hand side of Eq. (44) to zero, we obtain the ZK equation. Thus, our problem differs from the ZK equation through the coupling to the field Ψ . The linearized versions of the ZK equation and Eq. (44) are the same. Moreover, as we shall see, the 1D solitons are unstable in our problem, just as they are for the ZK equation [21–25]. However, there are important differences between the two problems: the growth rate of a perturbation of small transverse number k will be shown to increase as k^2 in our problem. In contrast, this growth rate is proportional to $|k|$ for small k in the case of the ZK equation.

4 Multiple scale perturbation analysis

To prepare to investigate the stability of the soliton described by Eqs. (49) and (50), we shall transform to a coordinate system that moves along with the soliton, and rescale so that the soliton amplitude is independent of a . Specifically, we set $X - X_0 = a^{-1}(\tilde{X} + 4\tilde{T})$, $Y = a^{-1}\tilde{Y}$, $T = a^{-3}\tilde{T}$, $u = a^2\tilde{u}$, and $\Psi = a\tilde{\Psi}$ in Eqs. (44) and (45). We shall again drop the tildes, and, in addition, replace X , Y and T by x , y and t . This yields

$$u_t - 4u_x + \nabla^2 u_x + \frac{1}{2}uu_x = -\frac{1}{2}(\Psi_x u_x + \Psi_y u_y) \quad (51)$$

and

$$\nabla^2 \Psi = u_x, \quad (52)$$

where $\nabla^2 \equiv \partial^2/\partial x^2 + \partial^2/\partial y^2$. The unperturbed one-dimensional soliton is given by

$$u_0 = 12 \operatorname{sech}^2 x \quad (53)$$

and

$$\Psi_0 = 12 \tanh x. \quad (54)$$

Note that

$$u_{0xxx} - 4u_{0x} + u_0 u_{0x} = 0; \quad (55)$$

we will need this identity later.

We now apply a sinusoidal perturbation with wavevector perpendicular to the direction of propagation: we put

$$u = u_0 + \epsilon f(x) e^{iky + \gamma t} \quad (56)$$

and

$$\Psi = \Psi_0 + \epsilon \rho(x) e^{iky + \gamma t} \quad (57)$$

and work to order ϵ . Eq. (51) becomes

$$\frac{d}{dx} \hat{L} f - k^2 f_x - \frac{1}{2} u_{0x} (f - \rho_x) = -\gamma f, \quad (58)$$

where $\hat{L} \equiv d^2/dx^2 + u_0 - 4$. From Eq. (52) we obtain

$$\rho_{xx} - k^2 \rho = f_x. \quad (59)$$

We are interested in the effect of *localized* perturbations to the 1D soliton. Therefore, we shall seek solutions to Eqs. (58) and (59) with the following properties: we require that

$$f \rightarrow 0 \text{ as } x \rightarrow \pm\infty \quad (60)$$

and

$$\rho_x \rightarrow 0 \text{ as } x \rightarrow \pm\infty. \quad (61)$$

We can obtain an approximate solution to Eqs. (58) - (61) if we restrict our attention to perturbations with small transverse wavenumber k and make a perturbation expansion in powers of k [27]. There is a technical difficulty, however. In a standard perturbation analysis, we would set

$$f = f_0 + k f_1 + k^2 f_2 + \dots, \quad (62)$$

$$\rho = \rho_0 + k \rho_1 + k^2 \rho_2 + \dots \quad (63)$$

and

$$\gamma = k \gamma_1 + k^2 \gamma_2 + \dots \quad (64)$$

(The zeroth order term in the expansion (64) vanishes because $\gamma = 0$ for $k = 0$ [17,18].) We would then insert Eqs. (62) - (64) in Eqs. (58) and (59) and equate the coefficients of like powers of k . Problems begin at the second order in the perturbation expansion: f_2 cannot be made to vanish for both $x \rightarrow +\infty$ and $x \rightarrow -\infty$. The difficulties grow still worse after this point, since f_3 and higher order terms diverge for large x .

To overcome these difficulties, we will employ a multiple scale perturbation analysis [28]. Our method is closely related to the multiple scale analysis developed by Allen and Rowlands for the ZK equation [25].

The basic problem is that even though k is small, x can be large. In our multiple scale analysis, we develop asymptotic expansions for f and ρ . If we keep terms of increasingly higher order in these expansions, we obtain approximate expressions for f and ρ valid for larger and larger values of x . To begin, we set $x_n \equiv k^n x$ for $n \geq 1$, and consider x , x_1 , x_2 , and so forth to be independent variables. Thus, f and ρ are considered to be functions of x and all of the x_i 's, and for small k we have

$$f = f_0(x, x_1, x_2, \dots) + k f_1(x, x_1, x_2, \dots) + k^2 f_2(x, x_1, x_2, \dots) + \dots, \quad (65)$$

and

$$\rho = \rho_0(x, x_1, x_2, \dots) + k \rho_1(x, x_1, x_2, \dots) + k^2 \rho_2(x, x_1, x_2, \dots) + \dots \quad (66)$$

Using the chain rule, we see that

$$\frac{d}{dx} = \frac{\partial}{\partial x} + k \frac{\partial}{\partial x_1} + k^2 \frac{\partial}{\partial x_2} + \dots \quad (67)$$

We insert Eqs. (65) - (67) and (64) into Eqs. (58) and (59) and equate coefficients of like powers of k . To completely determine the f_i 's and ρ_i 's, additional constraints must be imposed. We shall require that f_m/f_{m-1} remain bounded as $x \rightarrow \infty$ for all $m \geq 1$ [28]. This ensures that $k^m f_m$ is small compared to $k^{m-1} f_{m-1}$.

Since f and $\partial_x \rho$ tend to zero as $x \rightarrow \infty$, we demand that

$$f_m \rightarrow 0 \quad \text{as } x \rightarrow \infty \quad (68)$$

and

$$\partial_x \rho_m \rightarrow 0 \quad \text{as } x \rightarrow \infty \quad (69)$$

for all $m \geq 0$. Following Allen and Rowlands [25], we shall also insist that

$$e^{2x} f_m \rightarrow 0 \quad \text{as } x \rightarrow -\infty \quad (70)$$

for all $m \geq 0$. The resulting expressions for $f = f_0 + k f_1 + k^2 f_2 + \dots$ and $\partial_x \rho = \partial_x \rho_0 + k \partial_x \rho_1 + k^2 \partial_x \rho_2 + \dots$ will tend to zero as $x \rightarrow -\infty$, in accord with the boundary conditions (60) and (61).

If we retain n terms in each of the asymptotic expansions (65) and (66), we obtain expressions for f and ρ valid for x as large as k^{-n} [28]. To show that the 1D solitons are unstable, we will need to work to order $n = 3$. For convenience, we will write $f_{0x} \equiv \partial f_0 / \partial x$, $f_{01} \equiv \partial f_0 / \partial x_1$, $f_{0x1} \equiv \partial^2 f_0 / \partial x \partial x_1$ and so on.

Before embarking on the multiple scale perturbation analysis in earnest, we note that for large $|x|$, the problem simplifies considerably. Eq. (58) reduces to

$$f_{xxx} - (4 + k^2)f_x + \gamma f = 0 \quad (71)$$

in this limit. Since $\gamma = O(k)$, the general solution to Eq. (71) is a linear combination of $e^{p_1 x}$, $e^{-p_2 x}$ and $e^{p_3 x}$, where

$$p_1 = 2 - \frac{1}{8}\gamma + O(k^2), \quad (72)$$

$$p_2 = 2 + \frac{1}{8}\gamma + O(k^2), \quad (73)$$

and

$$p_3 = \frac{1}{4}\gamma + O(k^3). \quad (74)$$

Recall that f must vanish for $x \rightarrow \pm\infty$. Therefore, for large positive x ,

$$f \cong A_+ e^{-p_2 x} + B_+ e^{p_3 x}, \quad (75)$$

while, for large negative x ,

$$f \cong A_- e^{p_1 x} + B_- e^{p_3 x}. \quad (76)$$

Note that if the real part of p_3 is positive, B_+ must vanish, and, similarly, B_- must be zero if the real part of p_3 is negative. Eq. (76) will later provide a check of our analysis.

4.1 Zeroth order

To zeroth order, Eq. (58) becomes

$$\partial_x L f_0 - \frac{1}{2} u_{0x} (f_0 - \partial_x \rho_0) = 0, \quad (77)$$

where

$$L \equiv \frac{\partial^2}{\partial x^2} + u_0 - 4. \quad (78)$$

[Note that $\hat{L}$ and L differ: the partial derivative with respect to x appears in Eq. (78), whereas it is the total derivative with respect to x that appears in the definition of $\hat{L}$.] Eq. (59) yields $\partial_x^2 \rho_0 = \partial_x f_0$, which may be integrated to give $\partial_x \rho_0 = f_0 + c_0$, where $c_0 = c_0(x_1, x_2, \dots)$ is independent of x . Eqs. (68) and (69) show that c_0 must vanish. Hence

$$\rho_{0x} = f_0 \quad (79)$$

and Eq. (77) reduces to

$$\partial_x L f_0 = 0. \quad (80)$$

This is a third order ordinary differential equation for f_0 ; the general solution is

$$f_0 = h_0 \operatorname{sech}^2 x \tanh x + A_0 \chi + B_0 \cosh^2 x, \quad (81)$$

where

$$\chi \equiv \frac{1}{4} (3x \operatorname{sech}^2 x \tanh x - 3 \operatorname{sech}^2 x + 1). \quad (82)$$

h_0 , A_0 and B_0 are independent of x , but they may be functions of the x_n 's with $n \geq 1$. Because f_0 must tend to zero for $x \rightarrow +\infty$, the coefficients A_0 and B_0 must vanish. We conclude that

$$f_0 = h_0 F_0, \quad (83)$$

where $F_0 \equiv \operatorname{sech}^2 x \tanh x$. Eq. (79) now gives $\rho_0 = -\frac{1}{2} h_0 \operatorname{sech}^2 x + c'_0$, where c'_0 is independent of x . Choosing the potential zero appropriately, we can arrange

to have $c'_0 = 0$, and then

$$\rho_0 = -\frac{1}{2}h_0\text{sech}^2x. \quad (84)$$

4.2 First order

We next work to first order in k . Using the identity $LF_0 = 0$, Eq. (58) yields

$$\partial_x Lf_1 = -2f_{0xx1} + \frac{1}{2}u_{0x}(f_1 - \rho_{1x} - \rho_{01}) - \gamma_1 f_0. \quad (85)$$

Eq. (59) becomes $\rho_{1xx} + 2\rho_{0x1} = f_{1x} + f_{01}$. Using Eqs. (83) and (84) and integrating with respect to x , we find that

$$f_1 - \rho_{1x} - \rho_{01} = c_1, \quad (86)$$

where $c_1 = c_1(x_1, x_2, \dots)$ is independent of x . This allows us to simplify Eq. (85); we find that

$$\partial_x Lf_1 = -2h_{01}F_{0xx} - (\gamma_1 h_0 + 12c_1)F_0. \quad (87)$$

Eq. (87) has the solution

$$f_1 = -h_{01}xF_0 + \frac{1}{24}\gamma_1 h_0 + \frac{1}{2}c_1 + A_1\chi + B_1\cosh^2x, \quad (88)$$

where $A_1 = A_1(x_1, x_2, \dots)$ and $B_1 = B_1(x_1, x_2, \dots)$ do not depend on x .¹ Since f_1 must tend to zero as $x \rightarrow \infty$, the coefficient B_1 is zero. Eq. (88) is therefore

$$f_1 = \left(\frac{3}{4}A_1 - h_{01}\right)xF_0 - \frac{3}{4}A_1\text{sech}^2x + \frac{1}{4}A_1 + \frac{1}{24}\gamma_1 h_0 + \frac{1}{2}c_1. \quad (89)$$

Now f_1/f_0 must remain bounded as $x \rightarrow \infty$; as a result

$$A_1 = \frac{4}{3}h_{01}, \quad (90)$$

¹ Strictly speaking, a term proportional to F_0 should appear on the right hand side of this equation. However, if this term is included, the sole effect is to alter f and ρ by an irrelevant constant prefactor. Therefore, without loss of generality, we may omit this term.

$$c_1 = -\frac{1}{2}A_1 - \frac{1}{12}\gamma_1 h_0, \quad (91)$$

and Eq. (89) reduces to

$$f_1 = -h_{01} \operatorname{sech}^2 x. \quad (92)$$

Using Eq. (90) to eliminate A_1 from Eq. (91), we find that

$$h_{01} + \frac{1}{8}\gamma_1 h_0 + \frac{3}{2}c_1 = 0. \quad (93)$$

We now turn our attention to Eq. (86). Using Eqs. (84) and (92), we obtain $\rho_{1x} = -\frac{1}{2}h_{01}\operatorname{sech}^2 x - c_1$. The boundary condition (69) is satisfied only if $c_1 = 0$; Eq. (93) therefore becomes

$$h_{01} = -\frac{1}{8}\gamma_1 h_0. \quad (94)$$

We conclude that

$$f_1 = \frac{1}{8}\gamma_1 h_0 \operatorname{sech}^2 x \quad (95)$$

and

$$\rho_{1x} = \frac{1}{16}\gamma_1 h_0 \operatorname{sech}^2 x. \quad (96)$$

We integrate the latter equation with respect to x and choose the potential zero so that $\rho_1 \rightarrow 0$ as $x \rightarrow \infty$. This yields

$$\rho_1 = \frac{1}{16}\gamma_1 h_0 (\tanh x - 1). \quad (97)$$

4.3 Second Order

Equating coefficients of terms of second order in k in Eq. (58) and using the identity $LF_0 = 0$, we have

$$\begin{aligned} \partial_x Lf_2 = & -2f_{1xx1} - 3f_{0xx11} - 2f_{0xx2} - Lf_{11} + f_{0x} \\ & + \frac{1}{2}u_{0x}(f_2 - \rho_{2x} - \rho_{11} - \rho_{02}) - \gamma_1 f_1 - \gamma_2 f_0. \end{aligned} \quad (98)$$

Eq. (59) yields

$$f_{2x} - \rho_{2xx} - \rho_{1x1} - \rho_{0x2} = \frac{1}{2}h_0\text{sech}^2x; \quad (99)$$

this result has been simplified using the fact that $c_1 = 0$ and Eqs. (79), (84), and (86). Integrating Eq. (99) with respect to x , we obtain

$$f_2 - \rho_{2x} - \rho_{11} - \rho_{02} = \frac{1}{2}h_0 \tanh x + c_2, \quad (100)$$

where $c_2 = c_2(x_1, x_2, \dots)$. We now insert Eqs. (83), (84), (94), (95), (97) and (100) into Eq. (98). This gives

$$\begin{aligned} \partial_x Lf_2 = & \left(1 - \frac{7}{64}\gamma_1^2\right) h_0 F_{0x} - 2h_{02}F_{0xx} - (\gamma_2 h_0 + 12c_2)F_0 \\ & - \frac{1}{96}\gamma_1^2 h_0 u_0 + \frac{1}{768}\gamma_1^2 h_0 L u_0 - 6h_0 F_0 \tanh x. \end{aligned} \quad (101)$$

The last two terms on the right hand side of Eq. (101) must be rewritten before we can proceed further. To begin, note that Eq. (55) can be integrated to yield

$$u_0^2 = 8u_0 + 48F_{0x}. \quad (102)$$

Using this identity, it can readily be shown that

$$L u_0 = 24F_{0x} + 4u_0 \quad (103)$$

and

$$36F_0 \tanh x = u_0 - 12F_{0x}. \quad (104)$$

Eq. (101) now becomes

$$\begin{aligned} \partial_x Lf_2 = & \left(3 - \frac{5}{64}\gamma_1^2\right) h_0 F_{0x} - 2h_{02}F_{0xx} - \frac{1}{6}\left(1 + \frac{1}{32}\gamma_1^2\right) h_0 u_0 \\ & - (\gamma_2 h_0 + 12c_2)F_0. \end{aligned} \quad (105)$$

Eq. (105) has the solution

$$f_2 = -\frac{1}{6} \left(\frac{2}{5} + \frac{3}{64} \gamma_1^2 \right) h_0 \cosh x \sinh x + \frac{1}{10} \left(3 - \frac{5}{64} \gamma_1^2 \right) h_0 \tanh x + \frac{1}{24} (\gamma_2 h_0 + 12c_2) - h_{02} x F_0 + A_2 h_0 \chi + B_2 \cosh^2 x, \quad (106)$$

where $A_2 = A_2(x_1, x_2, \dots)$ and $B_2 = B_2(x_1, x_2, \dots)$ do not depend on x .²

Because f_2 must satisfy the boundary conditions (68) and (70), the coefficients of $\cosh x \sinh x$ and $\cosh^2 x$ in Eq. (106) must vanish:

$$\gamma_1^2 = -\frac{128}{15} \quad (107)$$

and

$$B_2 = 0. \quad (108)$$

Eq. (106) now reduces to

$$f_2 = \frac{11}{30} h_0 \tanh x + \frac{1}{24} (\gamma_2 h_0 + 12c_2 + 6A_2 h_0) + \left(\frac{3}{4} A_2 h_0 - h_{02} \right) x F_0 - \frac{3}{4} A_2 h_0 \operatorname{sech}^2 x. \quad (109)$$

f_2 must tend to zero as $x \rightarrow \infty$, and therefore

$$\left(\frac{44}{5} + \gamma_2 + 6A_2 \right) h_0 + 12c_2 = 0. \quad (110)$$

Since f_2/f_1 must remain bounded as $x \rightarrow \infty$, we must also have

$$h_{02} = \frac{3}{4} A_2 h_0. \quad (111)$$

All of the terms on the left hand side of Eq. (100) tend to zero for $x \rightarrow \infty$, and so

$$c_2 = -\frac{1}{2} h_0. \quad (112)$$

Eliminating c_2 from Eq. (110) using this result and A_2 using Eq. (111), we obtain

$$h_{02} = -\frac{1}{4} \left(\frac{7}{5} + \frac{1}{2} \gamma_2 \right) h_0. \quad (113)$$

² Footnote 1 again applies.

Eq. (109) can now be simplified using Eqs. (110), (111), and (113). We find that

$$f_2 = \frac{1}{4} \left(\frac{7}{5} + \frac{1}{2} \gamma_2 \right) h_0 \operatorname{sech}^2 x + \frac{11}{30} h_0 (\tanh x - 1). \quad (114)$$

Notice that although $e^{2x} f_2$ tends to zero as $x \rightarrow -\infty$, f_2 itself does not vanish in that limit.

We can now determine ρ_{2x} using Eqs. (84), (94), (97), (112), (113), and (114) in Eq. (100). The result is

$$\rho_{2x} = \frac{1}{8} \left(\frac{7}{5} + \frac{1}{2} \gamma_2 \right) h_0 \operatorname{sech}^2 x - \frac{1}{5} h_0 (\tanh x - 1). \quad (115)$$

Integrating this and choosing the potential zero to be at $x = +\infty$, we have

$$\rho_2 = \frac{1}{8} \left(\frac{7}{5} + \frac{1}{2} \gamma_2 \right) h_0 (\tanh x - 1) - \frac{1}{5} h_0 (\ln \cosh x - x + \ln 2). \quad (116)$$

4.4 Third Order

Using the identity $LF_0 = 0$ once again and equating coefficients of terms of order k^3 in Eq. (58), we have

$$\begin{aligned} & \partial_x Lf_3 + \partial_{x_1} Lf_2 + \partial_{x_2} Lf_1 + 2f_{2xx1} + 3f_{1x11} + 2f_{1xx2} + 2f_{0xx3} + 6f_{0x12} \\ & + f_{0111} - f_{1x} - f_{01} + 12F_0(f_3 - \rho_{3x} - \rho_{21} - \rho_{12} - \rho_{03}) \\ & = -(\gamma_1 f_2 + \gamma_2 f_1 + \gamma_3 f_0). \end{aligned} \quad (117)$$

From Eq. (59), we obtain

$$\begin{aligned} & \rho_{3xx} + 2\rho_{2x1} + 2\rho_{1x2} + \rho_{111} + 2\rho_{0x3} + 2\rho_{012} - \rho_1 \\ & = f_{03} + f_{12} + f_{21} + f_{3x}. \end{aligned} \quad (118)$$

This result can be simplified using Eqs. (79), (86), and (100), and the values of c_1 and c_2 . This gives

$$f_{3x} - \rho_{3xx} - \rho_{2x1} - \rho_{1x2} - \rho_{0x3} = 0, \quad (119)$$

and, integrating, we obtain $f_3 - \rho_{3x} - \rho_{21} - \rho_{12} - \rho_{03} = c_3$, where $c_3 = c_3(x_1, x_2, \dots)$. Now ρ_0 , ρ_1 , and ρ_2 tend to zero as $x \rightarrow +\infty$, and f_3 and ρ_{3x} must vanish in this limit as well. Thus, $c_3 = 0$ and

$$f_3 - \rho_{3x} - \rho_{21} - \rho_{12} - \rho_{03} = 0. \quad (120)$$

We now return to Eq. (117). Using Eq. (120) and our explicit expressions for γ_1^2 , h_{01} , h_{02} , f_0 , f_1 , and f_2 , we obtain

$$\begin{aligned}
-\partial_x L f_3 = & \frac{11}{20} \gamma_1 h_0 (\tanh x - 1) + \frac{1}{48} \gamma_1 \left(\frac{11}{5} + \frac{1}{2} \gamma_2 \right) h_0 u_0 \\
& + \left(\frac{13}{60} \gamma_1 + \gamma_3 \right) h_0 F_0 + \frac{5}{16} \left(\frac{7}{5} + \frac{1}{2} \gamma_2 \right) \gamma_1 h_0 F_{0x} \\
& + 2 h_{03} F_{0xx}.
\end{aligned} \tag{121}$$

The solution to this equation is

$$\begin{aligned}
-f_3 = & \frac{1}{4} \left(\gamma_2 - \frac{8}{15} \right) \gamma_1 h_0 \cosh x \sinh x \\
& + \frac{11}{80} \gamma_1 h_0 \left[\frac{1}{4} u_0 (\ln \cosh x - x - 1) \right. \\
& + 3 F_0 \left(\frac{1}{2} x^2 - \int_0^x \ln \cosh x' dx' \right) + x - \ln \cosh x \left. \right] \\
& + \frac{1}{24} \left(\frac{251}{60} \gamma_1 - \gamma_3 \right) + \frac{1}{16} \left(\frac{1}{4} \gamma_2 - \frac{13}{5} \right) \gamma_1 h_0 \tanh x \\
& + h_{03} x F_0 + A_3 h_0 \chi + B_3 \cosh^2 x,
\end{aligned} \tag{122}$$

where A_3 and B_3 are independent of x .³ Applying the boundary conditions (68) and (70) with $m = 3$, we see that B_3 vanishes and

$$\gamma_2 = \frac{8}{15}. \tag{123}$$

Eq. (123) is the principal result of this section. We have now shown that the one-dimensional solitons are unstable.

We must still show that our approximate solution can be given the correct asymptotic behavior. We require that $f_3 \rightarrow 0$ as $x \rightarrow +\infty$ and that f_3/f_2 remain bounded in this limit. This yields

$$\begin{aligned}
f_3 = & \frac{11}{80} \gamma_1 h_0 \left[-\frac{1}{4} u_0 \ln(1 + e^{-2x}) + 3 F_0 \int_0^x \ln(1 + e^{-2x'}) dx' + \ln(1 + e^{-2x}) \right] \\
& + \frac{37}{240} \gamma_1 h_0 (\tanh x - 1) + \frac{1}{96} \left(\gamma_3 + \frac{169}{60} \gamma_1 \right) h_0 u_0.
\end{aligned} \tag{124}$$

³ Footnote 1 again applies.

If x is large in magnitude and negative,

$$\frac{f_3}{h_0} = -\frac{11}{40}\gamma_1 x + O(1). \quad (125)$$

$e^{2x}f_3$ vanishes for $x \rightarrow -\infty$, but f_3 does not.

Suppose that x is large and negative, k is small, and kx is of order 1. Dropping terms of order e^{2x} , we have $f_0/h_0 = f_1/h_0 = 0$ and $f_2/h_0 = -11/15$. Eq. (94) shows that

$$h_0 = \exp\left(-\frac{1}{8}\gamma_1 x_1\right) h_1, \quad (126)$$

where $h_1 = h_1(x_2, x_3, \dots)$. In the limit we are presently considering, h_1 is approximately constant. Using these results and Eq. (125), we obtain

$$\begin{aligned} f &= f_0 + kf_1 + k^2 f_2 + k^3 f_3 + \dots \\ &\cong -\frac{11}{15}h_1 k^2 \exp\left(-\frac{1}{8}k\gamma_1 x\right) \left(1 + \frac{3}{8}k\gamma_1 x\right) + k^4 f_4 + \dots \end{aligned} \quad (127)$$

Retaining terms up to third order in k , this may be written

$$f \cong -\frac{11}{15}h_1 k^2 \exp\left(\frac{1}{4}\gamma x\right). \quad (128)$$

This is consistent with Eq. (76), and so f does indeed have the correct asymptotic behavior in the $x \rightarrow -\infty$ limit.

5 Conclusions

In this paper, we found the equations of motion for small amplitude, long waves on the surface of a current-carrying metal film. In dimensionless units, the equations are

$$u_T + (\partial_X^2 + \partial_Y^2)u_X + \frac{1}{2}uu_X = -\frac{1}{2}(\Psi_X u_X + \Psi_Y u_Y) \quad (129)$$

and

$$\Psi_{XX} + \Psi_{YY} = u_X. \quad (130)$$

These equations represent a generalization of the KdV equation to two dimensions, and seem not to have been studied previously.

1D solitons traveling over the surface of a current-carrying metal thin film were shown to be unstable. The growth rate for perturbations of small transverse wavevector k is

$$\text{Re } \gamma = \frac{8}{15}k^2 + O(k^3). \quad (131)$$

For the ZK [21–25] and KPII [19] equations, the growth rate $\text{Re } \gamma$ increases much faster than this as k is increased: it is proportional to $|k|$ for small k .

The linear stability analysis carried out in this paper only applies shortly after the 1D soliton is perturbed. What is the nature of the subsequent time evolution? For the ZK equation, it is known that if a 1D soliton is perturbed, it will break up into a series of “cylindrical” solitons [29]. These solitons are propagating humps, and are stable. Numerical studies of Eqs. (129) and (130) are currently underway, and will reveal whether a 1D soliton propagating over a current-carrying metal surface breaks up in a similar fashion after it has been perturbed.
